Look! Up on the hill! It's a bug! It's a worm! No! It's...
1PEED! CENTIPEED! CENTIPEED! CENTIPEED! CENTIPEED! CEN

The popular SLACK arcade game is here for the APF!
Now \$9.95

LIGHT-TRACER

Maneuver the "light tracer" within the screen boundaries.
Now \$6.95

THREE-FOR-ONE

1)SPACE WARS-You seal an opponent battle in outer space.
2)AIR FORTRESS-Wreck the fortress from the Komakaze aliens.
3)SHREVE PLAY-Get every block moving to escape the room!
All three now \$9.95

THE SEARCH

Explore the land in this fast adventure game. Find the magic sword and hood (if you can!) & then travel through time to defeat the villain (the planned dragon). The path is not easy! You must take obstacles such as dragons, Mother Nature, and other monsters. It's an adventure that uses two-word commands which you might find useful.

Only \$9.95

*****ROGUE** by James CHAN*******

SIG-TRIP

Hunt down and destroy the enemy in the different sectors of the galaxy. All commands are three letters. Special features are found in this game. E.g., if your weapons are damaged, you don't get a correct view of the sector. If your lasers are damaged, you lose half of your firepower. If your engines are damaged, you are slowed in speed. Specific manual version for those with Intellivision.

Only \$9.95

A Copyright from G.B. Award for CENTIPEED! 1st

*Congratulations on your good game!

Use all you get there in COMPUTER land! Have you not a creative program idea that you think would sell? Send it to me! You will be given credit for the idea/program and PAID if I use it. It will be advertised and distributed through me. Revenue you will be dependent on market price and time etc. All copyrights/ideas will be subject to some changes.

GENERAL NEWS

SPECIAL THANKS!

To **BILL BOWMAN**, **LOUIS DOOLEY**, and **HAL BLOOM** for supplying the club with programs that appear in this issue and in the CLUB PROGRAM LIBRARY.

Listed below is a brief explanation of each program submitted.

BILL BOWMAN-A program that will compare the cost of fuel--OIL vs GAS vs ELECTRIC. Club program designation T6FUELCOMP.

HAL BLOOM-A HARD COPY ONLY of a musical program that contains 14 different tunes that is set up to pull each tune from disk and RUN it. This program is a LIBRARY SELECTION but IS NOT on tape or disk. Eleven pages will be reproduced and sent to you, and counted as ONE selection. The minimum library order is 3, so your other two selections will be sent on cassette. Library designation ECDISKMUS

LOUIS DOOLEY-"APP IM-1 TYPEWRITER Jr." This program allows the user to type data, messages, records, etc. to the screen and store many screens to tape. Reviewing each screen is done by simply tapping the space bar. The menu explains the functions of the program. BK. Designation T6TYJR.

BILL BOWMAN-A program that will indicate HOW LONG a fixed sum of money, earning a fixed interest rate, would last at a specified monthly withdrawal. Designation T6FINWDL.

CORRECTION TIME!

An error (typo) that appeared in the JULY ARCADE is a good example of what happens when EXTREME CARE is not taken when LISTING or ENTERING ML DATA. In this case, I mistyped the very last byte in the short program at address A425. The data entered should have been 0A rather than 04. For those of you who did not catch it in the written instructions and entered the data as it appeared, found your WHITE SQUARE to be QUITE INACTIVE! The intent of the program was to display movement, with delay, from the top of the screen to the bottom.

MARCH-HELPFUL HINTS-WIRING FOR THE OLDER TYPE GEMINI 10 PRINTERS.

The lead designation should have been PIN 8 to PIN 8 rather than PIN 1 to 8.

CLARIFICATION

JULY ISSUE-PROGRAM "PAIRED ITEMS"

The article was weighted heavily with technical information about the operation of the program itself but should have included a brief description of what the program actually IS!

It could be considered a game, more specifically "A MEMORY GAME". The player enters a chosen number of PAIRS that are related to each other such as, STATES/CAPITOLS, POUNDS/KILOGRAMS, DOLLARS/ENGLISH POUNDS, etc. After all pairs are entered, the program will give you the first word of the pair and see if you can match it with its associated word that you entered initially. This can be recalled on a RANDOM or ORDERED basis. The computer will keep track of the % of correct entries. There are many variations that can be achieved and more than one player can be included.

CLARIFICATION

JUNE ISSUE-DATA SHOP

As explained, the cable used with the VOLKSMODEM requires wiring changes. This is true only if an 'A' cable is ordered. We have just learned that if a 'B' cabl is ordered with the modem, NO WIRING CHANGE IS NECESSARY. Be sure to specify the 'B' cable when ordering this modem.

ARE YOU MISSING AN ISSUE?

If so, please let us know which month and we'll send one out to you promptly!

MAY Q & A TOSS UP..NO RESPONSE TO DATE!!!!

Please..take another look at the MAY issue Q & A TOSSUP section. If you could respond to ANY of the questions listed therein, we would ALL sincerely appreciate it!

HELPFUL HINTS

This first **HELPFUL HINT** comes to us from **FRED VANOVEREM**, Grand Rapids, MI. Fred writes: "I sent along a short program which can be used to convert a **NUMBER** to a **STRING** and back again. Since I keep all my bowling and golf league data as numbers, I have to use routines of this type to get strings for sorting. By concatenating the number strings with **NAMES**, **DISK RECORD POINTERS**, etc., I have been able to produce **ORDERED LISTS** for almost any type of data. Perhaps this routine would be of interest to others."

```
10 REM ....CONVERT A THREE DIGIT OR LESS NUMBER TO A STRING
15 DIM A$(2): REM ....DIMENSION A THREE CHARACTER STRING
20 INPUT "INPUT ANY NUMBER (0-999) :";N
25 N1= INT (N/100): REM ....GET HUNDREDS UNIT
30 A$(0)= CHR$( 48+N1): REM ....CONVERT TO STRING AND PLACE IN VARIABLE
35 N2= INT ((N-N1*100)/10): REM ....GET TENS UNIT
40 A$(1)= CHR$( 48+N2): REM ....TO STRING AND INTO VARIABLE
50 N3=N-N1*100-N2*10: REM ....GET ONES UNIT
55 A$(2)= CHR$( 48+N3): REM ....TO STRING AND INTO VARIABLE
60 PRINT "NUMBER ";N;" IS NOW STRING: ";A$
100 REM ....THIS ROUTINE WILL CONVERT THE STRING BACK TO A NUMBER
110 N4=( ASC (A$(0))-48)*100
115 N5=( ASC (A$(1))-48)*10
120 N6= ASC (A$(2))-48
125 N7=N4+N5+N6
130 PRINT "... AND AGAIN THE NUMBER: ";N7
```

The next **HELPFUL HINT** was supplied by **BILL BOWMAN**, So. Yarmouth, MA. The program is an example of selecting items from a menu without using an **INPUT** prompt and **RETURN KEY**. Line 70 is the key for this function which is also explained in the **APP BASIC LANGUAGE REFERENCE MANUAL**. Thank you Bill for sending the program in.

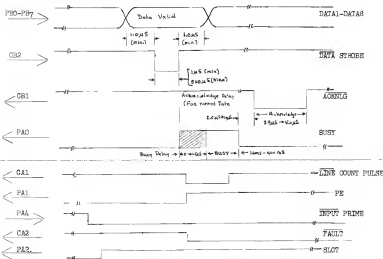

```

```

The next two pages contain the remainder of the **HARDWARE HINTS** on **CENTRONICS** interfacing, supplied by **DAVID PRESCOTT** of **A.I.T.** Thank you David!

Signal timing conditions for programming the parallel port.

Set up the parallel port in the following manner. Data register B side all outputs. Control register B-side in data handshake strobe mode, CB2 strobe-low, CB1 accept low pulse from ACKNLG. Because of the speed of the IM-1 clock the proper data set-up and strobe pulse durations should fall right within specifications. The acknowledge pulse from the printer will set the INCB1 bit in the B-side status register, so you know when to transmit the next character. Set up the A-side data direction register as PA0 - PA7 as inputs and PA4 as an output. PA4 will be used to output a low pulse INPUT PRIME to clear and activate the printer. PA0-PA7 will accept the BUSY, PE, SLOT, and OSCLT, if you should desire to use them in software control. Set the A-side Control register with CA1 and CA2 as inputs with active low edge trigger on both. CA1 will then set INCA1 every time the printer does a line feed so that you can keep track of what line you are on, on your paper. CA2 will set The INCA2 bit in the status reg. A should a fault occur on the printer.

Because the IM-1 does not have software to control a parallel printer interface it will be up to you to right the routine. It is most efficiently done in machine code, however it could be done in basic as well. Good luck and have fun.

All information in this article was addressed to the specifications supplied by Centronics Printer Manual Appendix B- Parallel Interface Specifications, to comply with the Centronics Interface characteristics, and matched to the IM-1 parallel port. A.L.T. will not be held responsible for any errors which may occur herein nor any damage to either units caused by user wiring errors or abuse. ■

The upper program was supplied by RUSSE NEWTHAM of DATABCOMP SOFTWARE and is the theme from HAPPY DAYS. The lower program is a sample of the many tunes submitted by HAL BLOOM. You'll recognize the tune immediately!

SHORT PROGRAMS

At last, a base conversion program that allows you to add, subtract, multiply, and divide in decimal, hexadecimal, octal, or split octal and have the ability to retrieve the answer in ANY of these bases that you desire! OUR THANKS TO LOUIS DOOLEY FOR THIS PROGRAM.

LEGAL EXPRESSIONS:

"N" = any number between 0 and 65535

"+" = math operator: + - * /

"C" = number base code:

T = DECIMAL (DEC) (=default code) the program defaults to DECIMAL

H = HEXADESIMAL (HEX)

O = OCTAL (OCT)

S = SPLIT OCTAL (OCS)

FORMATS

N=N=
+N=
N=C
CN=C
C
N+N=C
CN+CN=C
CN+N=
CN+N=C
N+CN=
N=CN=C
+N=C
+CN=
+CM=C

(SPACE PERMITTED ONLY IN SPLIT-OCTAL NUMBER)

("OUT OF RANGE" error print includes input or result greater than 65535 and improper characters) Note: Impractical to check for ALL possible errors in input; user must still be careful and prudent.

SAMPLE TEST DATA:

PRODUCT REVIEW

ESCAPE by ERIC BECKETT

This fast action HI RES game has been around for quite awhile but there have been a few inquiries about it lately. The game begins by placing you in a maze with no exits. You maneuver a HI RES character around the playing field and try to destroy FOUR security power banks by running over them with your man.

Roaming guards occupy the maze with you and will chase and fire bullets at you. You can fire back, and each guard that is destroyed is worth 10 points. If a guard runs over a spot where another guard was killed, a new guard is re-born and BOTH will chase you.

Guards in bunches are almost indestructible and your bullet will not usually penetrate them.

The walls that make up the maze are HIGHLY EXPLOSIVE. You must avoid running into them. You may not fire more than one bullet at a time. Your bullet must hit something and explode before you are able to fire again.

This game has several other distinct features that make it very interesting to play. It's a game that requires quick responses along with a VERY WATCHFUL EYE. The game comes with an instruction sheet and will work on both color and black and white sets.

A few more features to mention are:

If a dead bullet is blocking your way, DON'T run into it or you may BLOW UP! First shoot the dead bullet then go on through it. After firing, if you run after your own bullet, it will have a better chance of penetrating a guards bullet and destroy him. Try to remember where you kill guards and try to keep the live ones away from that area. It's easy to trick the guards into running into your bullet.

When a guard moves next to you, you must run up or down to escape. If you move right or left, you will most likely get napped by him!

Each security power bank that is destroyed is worth 100 points. Guards destroyed as mentioned are worth 10 points, and each NEW LEVEL that is achieved by eliminating guards in the preceeding level is worth an additional 1000 points. The game is written in MACHINE LANGUAGE for the play and BASIC for scoring. Some unique sounds are generated with the ML routines.

Note: The FRONT SCREEN (top left) indicates scoring provided in the game. Photo (bottom right) depicts the maze, power banks (objects that look like TV sets), the guards, FOUR MAN, and a few bullets (upper right).

NOT RECOMMENDED FOR THOSE WITH POOR PERIPHERAL VISION!!!!

PRODUCT REVIEW

TAPE ASSEMBLER from HEXMART

If you have been following the ARCADE section over the past months and have been looking up each OP code to find its meaning, you have probably found the task quite burdensome and time consuming. Eric mentioned an ASSEMBLER in the beginning of his instruction but decided to introduce you to the INSTRUCTION SET and use IT for a better understanding of MACHINE LANGUAGE PROGRAMMING. This is a proven method of instruction.

The HEXMART TAPE ASSEMBLER allows a person who is somewhat familiar with machine language to write 6800 assembly language programs without having to spend HOURS looking through the instruction set tables for the right OP codes to use, or counting in HEX to figure out the branching instructions.

The TAPE ASSEMBLER is a LINE ASSEMBLER in that it assembles each line of 6800 assembly code as it is typed in. As an example, if you need to LOAD ACCUMULATOR A with a value, the HEXMART program will look up the OP code for you in its memory and enter this data at a particular address for you automatically. You would simply be required to type in LDAA with the value you want loaded, indicating the addressing mode desired. This makes it a very fast method of writing machine language programs because the end result is actually in MACHINE LANGUAGE.

You might consider this assembler to be INTERPRETIVE, that is, it takes an input such as LDAA IM and interprets the correct HEX value that corresponds to the instruction. This value is then placed in consecutive addresses almost immediately thus causing the entire process to move swiftly and accurately. An important point to remember is that success with this assembler, as with any other, is based primarily upon the USERS KNOWLEDGE of machine instruction and experience with it. The program is written in BASIC with a machine language routine that searches through the entire built in instruction set table to find the correct OP code to use. The average time for the program to assemble a line of code is three to four seconds.

The TAPE ASSEMBLER is particularly useful for assembling relatively small programs but can also be used for larger ones since

it has capacity for 65 labels and 45 deferred operands in 8K.

The program comes with 27 pages of instruction that include an introduction to assembly language programming, how to use the assembler, work sheets, and information taken from the APF TECHNICAL REFERENCE MANUAL for further help in understanding assembly language programming. If you are serious about ML or assembly programming, the TAPE ASSEMBLER will take a lot of the chore out of the work. It is a common tool for virtually all programmers who work with machine language routines and programs.

Note: If you are just starting out in this area, you still need a good idea of how OP codes are used and what functions they perform. This is the intent of the ARCADE section. STAY WITH IT. In order to clearly understand Machine functions, the ARCADE should prove to be very helpful. After you have gotten a good grasp of programming directly, try the assembler and find out how much EASIER it makes the ENTIRE JOB!

THE ARCADE

WORK ARCADE DATA HAS ARRIVED! The MICRON wheel is ready to go in order to get as such in this issue as possible. Eric begins this issue with BRANCHING techniques.

If the program appearing in last month's issue was entered correctly you should see a square move smoothly across the screen from left to right and gradually from top to bottom. If not, check your inputs carefully and try again.

BRANCHING

The machine language branch statements are similar to BASIC IF THEN GO TO. You are checking for a certain condition (depending upon which branch statement is used) and then branching (or jumping) if that condition is met. If it isn't, the program continues on.

Branch statements can be used after any instruction but usually after a compare instruction or a subtract command. It can also be used after an INCREMENT or DECREMENT command as in our previous program example. Branching is best used when you want to go to a relatively close location. The limits are around 128 bytes in either direction from where the program currently is at the time. If you're using a good ML ASSEMBLER your branches are automatically calculated. When using the APF monitor as we are in this instruction, you will have to count how far away you want to go by counting for yourself. If you branch a lot, far away from your current address, a lot of your time will be spent counting bytes. I suggest using the following trick when you want to go to a far location on a certain condition. Let's assume that you want to branch if a certain number is greater than zero. It would look like this in machine code:

```
01 COMPARE ACC, A IMMEDIATE
XX DATA TO COMPARE ACC, A to
02 BRANCH IF (ACC, A-XX) 0
03 WHERE TO BRANCH TO
XX PROGRAM CONTINUES
XX
```

In the example you will be branching 65 bytes FORWARD in the program from where you are. You can change the branch if greater than () 0 to branch if less than () 0. In this way if it is greater than 0 you SKIP and go to a JUMP instead. Look at the following example:

```
01 COMPARE ACC, A IMMEDIATE
XX
02 BRANCH IF LESS THAN 0
03 WHERE TO BRANCH TO
04 JUMP
XX TO THE LOCATION
XX 65 BYTES AWAY
```

This second example will save you time counting all those bytes!

We can branch forward and backward. Branch instructions are TWO bytes long, the second byte is called the OFFSET byte. This byte determines how far away we will branch, forward or backward. To branch forward just count the number of bytes to where you want to go. You DO NOT count the offset byte and the byte after it is number 00. Then comes 01, 02,.... etc. You can see how we did this in our example with the moving square. At A420 we wanted to branch over the return code of 39, so we used an offset value of 01. We can only branch forward to around 7F because to branch backwards we start at the offset of FF and count backwards FF, FE, FD, FC,.... We did this in our examples at step A105. We wanted to branch backwards to A410 or back 7 bytes, so we used an offset of FB. For convenience, the BRANCH CHART included in this issue should be helpful to you to figure your branching values.

Try experimenting with the moving square example. By changing the delay variable, you can get a real good feel of how fast ML is. There are two variables in accumulator A that are most effective. Start by changing the value at A40F from FF to 7F. This is about HALF THE DELAY from the original version. Do this by using the ML monitor command *M A40F FF 7F. Now, run the program. Notice the speed change from the original. Try changing A40F to 3F. Then try 0F. You will get to a point where it goes so fast across the screen that it no longer looks like the square is moving. It will appear to jump from one place to another.

JOYSTICKS

If you have ever written any games in BASIC, you know one of the most time consuming things to do is to READ the joystick's during the program operation. This problem is easily overcome using machine language. To make things easier, APF has included a routine in the ROM that reads the joystick's and places the results at an address. To use these routines we simply JUMP to them using a JUMP TO SUBROUTINE command. When the subroutine is done, it will automatically return to wherever it left off in the program.

To read the LEFT joystick, you would jump to the subroutine at 410E. Your computer now looks at the joystick. If anything is pressed, a BIT in the CONDITION CODE REGISTER called the CARRY BIT will be SET. This will be explained later. It also READS what was pressed on the joystick and stores the ASCII CODE for this value at address 01F2. Our program would then look at 01F2 to see what was pressed.

THE ARCADE

This is how we would use this subroutine:

First, clear the carry bit using the OP code 0C which is CLEAR CARRY. This is done to reset the joystick in case it was already moved once. We then jump to the joystick ROM routine as mentioned. When we come back from the ROM routine we use the OP code branch if the carry bit is set, or (25 in HEX). If we used the joystick, we would branch to another routine that reads location 01F2 to see which way the joystick was moved. If we wanted to read the RIGHT joystick, we would do the same thing, only JUMP to a different ROM routine which is located at 4109. The result would still be found at location 01F2. The result at location 01F2 is the ASCII equivalent. The values that can appear at location 01F2 will be as follows:

NORTH = 4E
SOUTH = 53
EAST = 45
WEST = 57
FIRE = 21

We can also use a ROM routine to get a key input from the MAIN KEYBOARD. It will not return a shifted key word such as the control key and top 2 rows. To use it simply jump to the subroutine at 80CF. When the program returns from the subroutine, the ASCII code for the key pressed will be in ACCUMULATOR A. If ACCUMULATOR A equals 0, then NO KEYS WERE PRESSED.

Next on Eric's agenda is a 150 byte machine language program that moves a white square using the joystick with the ROM routines. There is not enough room in this issue to accomodate the data, so, a small portion will appear herein and the remainder in next month's issue.

For this month, enter only the BASIC program that appears below and CGAVE this information to tape so that it may be retrieved easily for next month's instruction.

The first 3 BASIC lines contain 'A' characters after the REM statements. Enter the amount of 'A's shown AFTER the REM.

10REM (total of 51 letter A's)
15REM (total of 51 letter A's)
20REM (total of 50 letter A's)
25POKE 24578,38

30CALL17046
40CALL42002
45CALL42012
50GOTO45

BRANCH CHART

USE TOP AND LEFT FOR BACKWARD BRANCH
USE BOTTOM AND RIGHT FOR FORWARD BRANCH
COUNT THE NUMBER OF BYTES TO THE
TARGET INSTRUCTION..THEN
GO TO THE CHART

EXAMPLE OF BACKWARD BRANCH:

9 8 7 6 5 4 3 2 1
86 23 A7 00 8C 03 00 26 F7
of BYTES = 9 TOP & LEFT = F7

EXAMPLE OF FORWARD BRANCH: (Note where count begins)

86 33 A7 00 A7 01 8C 03 00 27 06
86 22 A7 04 A7 08 39
of BYTES = 6 BOTTOM & RIGHT = 06
EXAMPLES: FORWARD 122 = 7A
BACKWARD 111 = 91
FORWARD 33 = 21

DATA SHOP

Briefly, let's examine the last form of IM-1 to IM-1 communication..NEITHER IM-1 RUNNING A TERMINAL EMULATOR PROGRAM.

After the two computers are connected via modem, the transmitting end configures his IM-1 to PRINT TO THE LINE by typing in the statement PRINT=1. The receiving end relinquishes control of his IM-1 by reinitializing it in the PRINT=2 mode. At this point, the transmitting end has full control over the receiving end IM-1.

During our experimentation with this form of communication we found that normal PRINT and CONTROL statements can be sent to the distant end in the IMMEDIATE MODE ONLY, that is, the statements must be typed by the transmitting end without any program operation or influence. For example, to print the word HELLO, the transmitting end (in the PRINT=1 condition as mentioned previously) would merely type PRINT"HELLO" with a carriage return. The distant end would receive the word HELLO on his screen, but, because the word is INVALID by itself, his IM-1 will respond with the word WHAT. This is of no consequence when single sentence conversation is desired in this mode. Transmitting VALID statements as PROGRAM DATA requires a little bit more work and will be explained in detail.

Virtually ALL BASIC commands can be sent to the receiving end as long as they are included within a PRINT STATEMENT. Commands such as GRAVE, CLOAD, POKE, HLIN, VLIN, can also be transmitted to save information stored in the receiving ends memory, or to produce graphics on his screen. For example, to draw a horizontal line across the receiving end IM-1, the transmitting end would type PRINT"HLIN,30,1". Only the command HLIN,30,1 would be sent out to the receiving end. His IM-1 would interpret this command as a VALID statement and would produce a line across his screen providing the SHAPE and COLOR was established previously. To the receiving IM-1, this command would seem to have been from the keyboard directly, however, it produces the same results when coming in from the line. It seems a bit KEEPER to have someone else CONTROLLING YOUR computer!

If a musical score is to be sent for IMMEDIATE LISTENING, the transmitting IM-1 would include the music within a special print statement such as PRINT"MUSIC"123". Notice the use of an apostrophe at the beginning and end of the above statement. This allows the needed QUOTATION MARKS to accompany the MUSIC statement so that the receiving IM-1 accepts the command MUSIC"123". Any apostrophe will be eliminated from the transmitted data. This arrangement should also be used when sending line by line program data whenever QUOTES are needed. See example below.

As you can plainly see, there are many things that CAN be accomplished in this mode, but, in an extremely SLOW fashion. For transmitting program data (directly typed), it is much easier to use a terminal emulator program on the transmitting end.

NEXT MONTH: The conclusion of this article and a look at a few of the popular BULLETIN BOARD SYSTEMS throughout the country using TERM-1 with a printer bridged on the line at the same time. See you then!

SAMPLE PROGRAM THAT CAN BE TRANSMITTED TO THE DISTANT END, LINE BY LINE, THEN RUN ON THE DISTANT END COMPUTER.

```
PRINT"10PRINT"ITS TIME TO WAKE UP THERE"  
PRINT"20MUSIC"555666555444555"  
PRINT"30POKE=170500:NEXT"  
PRINT"40CALL17046"  
PRINT"50GOTO10"  
PRINT"RUN"
```

Notes As you type, the program will be entered into the distant IM-1's memory. The command RUN will cause the program to begin running on the distant end! To give control back to the receiving end, type the command PRINT"PRINT=0". The distant end will then be able to GRAVE the program and have full control once again.

MICROPROCESSOR GLOSSARY

ACCUMULATOR The register where arithmetic or logic results are held. Most MPU and system microprocessors use the accumulator to store results.

ACCESS TIME Time delay for specific byte of information to become available to processor.

ADDA Asynchronous Data Transfer Adapter Adapter Interface between microprocessor peripheral and an MPU.

ALU Arithmetic and Logic Unit. The part of the MPU where arithmetic and logic functions are performed.

ASCII American Standard Code for Information Interchange Binary code to represent alphanumeric, space and control characters.

ASSEMBLER Software which converts assembly language statements into machine code instructions for micro-processor or microcomputer.

ASSEMBLY LANGUAGE Means of representing programs syntactically in machine code and covers only handling memory addressing by use of symbolic labels.

ASYNCHRONOUS Operations that involve a new operation immediately upon completion of current one — not timed by system clock.

BASIC Beginner's All Purpose Symbolic Instruction Code. An entry to learn widely used high level language.

BAUD Measure of speed of transmission line. Number of times a line changes state per second. Used to test, per second, of each line state represents logic 0 or 1.

BALLOOT CODE 5 bit code used to encode alphanumeric data.

BCD Binary Coded Decimal. Means of representing decimal numbers where each figure is replaced by a binary equivalent.

BENCHMARK A common task for the implementation of which processors can be ordered for efficiency in order to determine the efficiency of the different MPU in the microprocessor application.

BRANCH The two basic number systems. The digits are 0 or 1. They are used to create a new path to represent the two states of an input circuit.

BIT A single binary digit.

BRANCHPOINT Program address at which execution will be halted to allow branching or data entry.

BUFFER Circuit to provide isolation between sensitive parts of a system and the rest of that system.

BUS A program error that causes the program to malfunction.

BUS The interconnections in a system that carry parallel binary data. Several bus units are connected to the bus but generally only one sender and one receiver are active at any one time.

BYTES A group of bits — the most common byte is eight bits.

CLOCK The basic timing for a MPU chip.

COMPILER Software which converts high level language statements into machine code instructions.

CPU Central processing unit. The part of a system which performs calculation and data manipulation functions.

CROM Central Read Only Memory.

CRIT Critical Error Type. Often taken to mean computer output device.

CUTS Computer User Time Groups. Definition of system for storing data on cassette tape in series of bytes to represent binary 1's and 0's.

DATA The process of checking and correcting any program errors either in writing or in actual function.

DETECT ADDRESSING An addressing mode where the address of the operand is contained in the instruction. (Addresses before 500 to 5000).

DMA Direct Memory Access.

DUPLEX Transfer of data in two directions simultaneously.

ENVIRONMENT The conditions of all registers, flags etc. entry system in program.

EPROM Electrically Programmable Read Only Memory. Memory that may be read directly by light under light and reprogrammed electrically.

EXECUTE To perform a sequence of program steps.

EXECUTION TIME The time taken to perform an instruction in terms of clock cycles.

FORMATS Instructions or data particularly stored on ROM.

FLAG A flip flop that may be set or reset under software control.

FLOP/FLOP Two state device that changes state when clocked.

FLOPPY DISK Mass storage which makes use of flexible disks made of a material similar to magnetic tape.

FLOW CHART A diagram representing the logic of a computer program.

GATE For logic pulse.

HALF DUPLEX Data transfer in two directions but only one way at a time.

HAND SHAKE System of data transfer between CPU and peripheral whereby CPU waits peripheral if it will accept data and only transfers data if answer is yes.

HARD COPY System output that is printed on paper.

HARDWARE All the electronic and mechanical components making up a system.

HAIRD WIRE Device that can compress of logic gates, wired together, the wiring gates determining the overall logic operation.

HASH Binary code.

HEXADECIMAL The base 16 number system. Character set is decimal 0 to 9 and letters A to F.

HIGH LEVEL LANGUAGE Computer language that is easy to use, but which requires compiling into machine code before it can be used by an MPU.

HIGHWAY An BUS.

IMMEDIATE ADDRESSING Addressing mode which uses part of the instruction itself as the operand.

INDEXED ADDRESSING A form of indirect addressing which uses an Index Register to hold the address of the operand.

INSTRUCTION ADDRESSING Addressing mode where the address of the location where the address of the operand may be found is contained in the instruction.

INSTRUCTION SET List of all registers, flag etc. to which instructions are directed.

INSTRUCTION Set of codes which may be supplied to an MPU to cause it to perform a particular function.

INSTRUCTION REGISTER MPU register which is used to hold instructions fetched from memory.

INSTRUCTION SET The repertoire of instructions that a given MPU can perform.

INTERFACE Device which connects different parts of a system together and performs any necessary logic or signal to signal to make transfers possible or avoid a possible conversion.

INTERPRETER An interpreter is a software routine which interprets and executes a high level language program, but does not compile it into a machine code machine code before but does not compile it into a machine code machine code before but does not compile it into a machine code machine code before.

INTERRUPT A signal to the MPU which will cause it to change from its present task to another.

I/O Input/Output.

KANGAROO CITY A signal to the MPU which will cause it to change from its present task to another.

LANGUAGE A systematic means of communicating with an MPU.

LATCH Retains previous input state until overrulen.

LIFO Last In First Out. Used to describe data stack.

LOOPING Program technique where data system of the loop is performed until a condition is met.

MACRO A macro is a sequence of instructions that can be used as a single instruction.

MEMORY The part of a system which stores data (excluding data at address input stage).

MEMORY MAP Chart showing the memory allocation of a system.

MEMORY MAPPER I/O. A technique of implementing I/O operations by addressing I/O ports as if they were memory locations.

MICRO CODE Single program step in an MPU.

MICRO PROGRAM The smallest level of machine program step.

MICRO PROCESSOR A CPU implemented by use of large scale integrated circuits.

MICRO PROGRAM Program inside MPU which controls the MPU chip during its basic instruction cycle.

MMIO Memory Management I/O.

MODEM Modulator/Demodulator used to send and receive serial data over the audio line.

NON VOLATILE Memory which will retain data contents after power supply is removed, e.g. ROM.

OUTPUT Data that is sent out to the system or the MPU on instructions and data.

OUT Open Collector. Means of logic together with a pull-up resistor device on the same bus.

OUT Data I/O number system. Character set is decimal 0-9.

OP CODE Operation Code. A bit pattern which specifies a machine operation in the CPU.

OPERAND Data used by machine operations.

PARALLEL Transfer of two or more bits at the same time.

PARITY Check for added in data can be used to even parity. In odd parity sum of data 1's is parity bit is 0.

PERIPHERAL Equipment for inputting to or outputting from the system (e.g., a keyboard, VDU etc.).

PIK Peripheral Interface Adapter.

POP Operation of removing data word from LIFO stack.

PORT A terminal with the MPU uses to communicate with the outside world.

PROGRAMS Set of MPU instructions which instruct the MPU to carry out a particular task.

PROGRAM LOCATOR A program which holds the address of next instruction for data word at the program being executed.

PROGRAM Program which holds primary forms in a general form of ROM which can be individually programmed by user.

PUSH Operation of putting data to LIFO stack.

RAMP Random Access Memory. A type of memory that can be used to store data in any location in the memory.

REGISTER General purpose MPU storage location that will hold one MPU word.

RELATIVE ADDRESSING Mode of addressing whereby address of operand is formed by adding current program count with a displacement value which is part of the instruction.

ROM Read Only Memory. Memory device which has its data content established as part of manufacturing and cannot be changed.

SEARCH I/O. Memory that has short access time and is used by systems for short term data storage.

SEMIPLX Transfer of data into and out of a byte.

SERIAL Data transmission in one direction only.

SOURCE I/O. Memory that has short access time and is used by systems for short term data storage.

STATUS REGISTER Register that is used to store the status of the microprocessor or microcontroller.

SWAP Exchange of data between two registers.

SYSTEM A sequence of instructions which perform an operation or function, which can be used to carry out any task in the microprocessor.

TASK A task is a sequence of instructions which perform an operation or function, which can be used to carry out any task in the microprocessor.

TRN Transfer of data between two registers.

UNIT A sequence of instructions which perform an operation or function, which can be used to carry out any task in the microprocessor.

VECTOR Memory address given to the processor to direct it to a new state in memory.

VOLATILE Memory devices that will lose data when power is removed.

WORD Parallel collection of binary digits much as byte.
